## Amendment "A"

Please cancel claims 21-29, without prejudice; please amend claims 9-11 and 16 as indicated below. The state of the claims following this Amendment "A" is as follows:

Claim 1 (original). A securing apparatus configured to secure a coupling of a first connector to a compatible second connector, the apparatus comprising:

a moveable securing member configured to be moved from a first position which prevents the first and second connectors from being decoupled, to a second position which allows the first and second connectors to be decoupled; and

an actuator configured to move the securing member between the first and second positions, the actuator being responsive to an authorization command.

Claim 2 (original). The securing apparatus of claim 1, and wherein the first connector defines a first receiving opening configured to receive the securing member, the second connector defines a second receiving opening configured to receive the securing member, and wherein when the connectors are coupled when the receiving openings are at least partially in alignment.

Claim 3 (original). The securing apparatus of claim 1, and wherein the actuator comprises a solenoid.

Claim 4 (original). The securing apparatus of claim 3, and wherein the solenoid is an electrical solenoid, and further wherein the solenoid is configured to move the securing member to the first position when the solenoid is under power.

Claim 5 (original). The securing apparatus of claim 1, and further comprising a securing member sensor configured to detect when the securing member is in the first or the second position, and to generate a position signal in response thereto.

Claim 6 (original). The securing apparatus of claim 5, and wherein the position signal is used to notify a user of the status of the securing member.

Claim 7 (original). The securing apparatus of claim 1, and wherein the authorization command is generated by a user.

Claim 8 (original). The securing apparatus of claim 1, and wherein the authorization command is generated automatically by a control unit, and wherein the control unit is configured to remove the first and second connectors from service prior to authorizing moving the securing member to the second position.

Claim 9 (currently amended). A system comprising an array of modules and a plane, each module having a first connector configured to couple with a compatible, corresponding second connector which is mounted to the plane, and at least one interlock device, the interlock device comprising a securing member configured to be moveable to a first position to engage an associated module and thereby arrest relative movement between the associated module's first connector and the corresponding second connector, the securing member being further configured to be moveable to a second position in response to an authorization command to disengage the associated module and thereby allow relative movement between the associated module's first connector and the corresponding second connector.

18

23

25

Claim 10 (currently amended). The system of claim 9, and further comprising an actuator configured to move the securing member between the first and second positions in response to the authorization command.

Claim 11 (currently amended). The system of claim 10, and further comprising a controller having a diagnostic program, the diagnostic program being configured to perform diagnostics on the associated module and to generate the authorization command as a service signal when the diagnostic program determines that the associated module should be physically removed from the system for service, and wherein the service signal is used to cause the actuator to move the securing member from the first position to the second position.

Claim 12 (original). The system of claim 11, and wherein the controller is further configured to cause the associated module to be removed from service with respect to the plane prior to causing the actuator to move the securing member from the first position to the second position.

Claim 13 (original). The system of claim 9, and further comprising a securing member sensor configured to detect when the securing member is in the first or the second position, and to generate a position signal in response thereto.

Claim 14 (original). The system of claim 13, and wherein the position signal is used to signal to a user whether the securing member is in the first or the second position.

Claim 15 (original). The system of claim 13, and wherein the securing member sensor is supported by the at least one module.

Claim 16 (currently amended). A method for securing a first connector to a second connector, comprising:

providing an arresting surface configured to restrict movement of the first connector when the arresting surface is contacted by a force applied to the first connector;

providing a moveable securing member which is configured to move between a first position and a second position in response to an authorization command;

moving the securing member to [[a]] the first position which allows relative movement between the connectors;

moving one of the connectors relative to the other connector to bring the connectors onto mating contact;

providing an authorization command to move the securing member from the first position to the second position; and

in response to the authorization command, moving the securing member to the second position in proximity to the arresting surface to thereby restrict relative movement between the first and second connectors.

Claim 17 (original). The method of claim 16, and further comprising detecting the position of the securing member, and reporting the position of the securing member to a controller.
